(54) Fluid measurement

(57) In measuring the amount of fluid contained in a tank (10), two values L_1 , L_2 related to the amount of fluid present are calculated, from information provided respectively by a level gauge 11 and a flowmeter 12. A calculating unit 14 resets the second value when the difference between the two values exceeds a given threshold. Also, a factor applied to the flowmeter output is modified depending on the difference existing between the two values. The display 17 displays the second value L_2 .

SPECIFICATION
Fluid measurement

The present invention relates to the measurement of the amount of fluid contained in a tank, particularly the amount of fuel present in the tank of a motor vehicle.

In the motor car field, the important development has been witnessed for some years of apparatus known as "car computers" which are intended to supply the driver with a large number of items of information, including average instantaneous consumption, cruising range, etc. Nevertheless, in order to ensure a correct operation of these apparatus and to facilitate the observation of these, it would be desirable to have available measuring systems which are precise and deliver stable information.

The more conventional devices for measuring the level of the fuel in the tank, such as devices with a float for example, cannot give satisfaction. Indeed, apart from problems associated with their complexity and poor reliability, these devices are very sensitive to the fluctuations in fuel level owing to disturbances, e.g. due to accelerations of the vehicle.

An attempt has been made to overcome this disadvantage by inserting the float in a tubular element which is disposed vertically and in communication with the tank through a calibrated orifice. Nevertheless, this arrangement proves relatively complex and it is found, in practice, that it does not provide sufficiently stable information.

Other devices have been proposed but these have been set aside particularly because of their high cost and technical complexity.

In accordance with this invention there is provided a method of measuring the amount of fluid contained in a tank, comprising:

- (a) measuring the level of the fluid in the tank by means of a gauge,
- (b) determining a first value $L_1(n)$ related to the amount of fluid present in the tank from a value L_0 representing the fluid level provided at a given moment (n) by the gauge and from a first value $(L_1(n-1))$ previously determined,
- (c) measuring the amount of fluid withdrawn from the tank per unit of time,
- (d) determining a second value L_2 related to the amount of fluid present in the tank from the measured flow rate, applying thereto a given factor (K);
- (e) comparing the values L_1 , L_2 , related to the amount of fluid, as determined in steps (b) and (d);
- (f) resetting the second value L_2 to equal the first value L_1 , each time the difference between these two values L_1 , L_2 exceeds a given threshold X, said second value (L_2) then representing the amount of fluid;
- (g) modifying the factor K applied to the measured flow rate for the calculation of said second value (L_2) in the step (d) depending on the difference existing between the first value L_1 and the second value L_2 ; and
- (h) repeating the steps (a) to (g).

The embodiment to be described herein is simple, robust, reliable and economical, while providing precise and stable information. In particular it makes use of a gauge and preferably a flowmeter, which devices are completely conventional in themselves. This embodiment enables the contents of the tank to be known in a precise and stable manner to supply the user of the car computer with stable information.

Other characteristics and advantages of the present invention will be apparent on reading the following detailed description with reference to the accompanying drawings, given by way of non-limiting example, and in which:

- 80 Figure 1 is a block diagram of a measuring device according to the present invention;
- Figure 2 is a diagrammatic flow chart illustrating the operation of the device according to the present invention;
- 85 Figure 3 represents curves which illustrate the various values determined by the device according to the present invention; and
- Figures 4a and 4b illustrate the value of the amount of fluid contained in the tank, as calculated by the device according to the present invention, in two particular cases.
- 90 As illustrated diagrammatically in Figure 1, the measuring device according to the present invention comprises a gauge 11 to measure the level of the fluid, or liquid, contained in the tank 10 of a vehicle, as well as a flowmeter 12 which measures the amount of fluid withdrawn from the tank per unit of time.
- 95 The information delivered by the gauge 11 is applied to a calculating unit 14 by means of an analogue/digital converter 13. Of course, it is easy to determine the number of litres of liquid contained in the tank 10, on the basis of the information delivered by the gauge 11, if the 100 dimensions and the shape of the tank 10 are known.
- 105 In a similar manner, the pulses delivered by the flowmeter 12 and representative of the flow of fuel, are applied to the calculating unit 14. There again, it is possible to determine the number of litres of fuel contained in the tank 10 on the basis of the information supplied by the flowmeter, if the 110 number of litres originally present in the tank 10 is known.
- 110 The measuring device according to the present invention likewise comprises two registers of stores 15 and 16, connected to the calculating unit 14. The first register 15 is adapted to store said first value (L_1) of the amount of fluid present 115 in the tank, determined by means belonging to the calculating unit 14, depending on the information representative of the fluid level, delivered by the gauge 11, weighting this information on the basis of a first value previously determined.
- 120 The second register 16 is adapted to store a second value (L_2) of the amount of fluid present in the tank, determined by means likewise belonging to the calculating unit 14, depending on the 125 information delivered by the gauge 11, weighting this information on the basis of a first value previously determined.
- 125 The second register 16 is adapted to store a second value (L_2) of the amount of fluid present in the tank, determined by means likewise belonging to the calculating unit 14, depending on the

Information (d) representative of the flow of fluid, delivered by the flowmeter 12, by applying a given factor (K) to this information.

As will be apparent on reading the following description, the calculating unit 14 likewise comprises means for comparing the aforesaid two values (L_1, L_2) of the amount of fluid and means for resetting the second value (L_2) when the difference between these values exceeds a given threshold, said resetting means making the second value (L_2) equal to the first (L_1) in such a manner that the second value represents the amount of fluid present in the tank. On the other hand, the calculating unit 14 comprises means for modifying the factor (K) applied to the information (d) delivered by the flowmeter 12 for the calculation of the second value, depending on the difference existing between the first (L_1) and the second value (L_2).

Finally, as illustrated in Figure 1, the device likewise comprises means 17 for displaying the second value L_2 representative of the amount of fluid present in the tank.

The method of measuring according to the present invention will now be described with reference to the flow chart illustrated in Figure 2.

When voltage is first applied and when the device is reset to zero, illustrated diagrammatically by the first step 50: " $L_0=L_1=L_2$ ", a value L_0 representative of the amount of fluid contained in the tank and calculated by the calculating unit 14 on the basis of the information delivered by the gauge 11 is transferred into the registers 15 and 16.

As illustrated by the step 51, the calculating unit 14 determines a first value $L_1(n)$ of the amount of fluid present in the tank depending on the information representative of the fluid level delivered at a given moment (n) by the gauge, weighting this information on the basis of a first value $L_1(n-1)$ determined previously. More precisely, as illustrated in Figure 2, the calculating unit 14 determines said first value L_1 , on the basis of the following formula:

$$45 \quad L_1(n) = \frac{(p-1)}{p} L_1(n-1) + \frac{L_0}{p}$$

in which:

- 50 $L_1(n)$ represents the first value L_1 at the moment n,
- $L_1(n-1)$ represents the first value L_1 at the moment (n-1),
- L_0 represents a datum proportional to the information representative of the fluid level delivered by the gauge,
- p represents any whole number.

55 Said first value L_1 , thus determined, is stored in the register 15 and reactuated sequentially, for example every second.

By way of non-limiting example, p may be equal to 16 which gives a response time

60 equivalent to 16 seconds and causes a lag of 0.2 litre for flows of 50 litres/hour.

As illustrated in Figure 3, in which there is represented a first curve L_0 representative of the amount of fluid contained in the tank, determined 65 on the basis of the information delivered by the gauge, as well as a curve L_1 , representative of said first value, this smoothing effected by the calculating unit 14 eliminates the rapid variations in the values recorded by the gauge 11 and due, 70 in particular, to the displacements and accelerations of the vehicle.

At the step 52, the calculating unit 14 determines a second value L_2 of the amount of fluid present in the tank depending on the 75 information d representative of the flow of fluid, delivered by the flowmeter 12, applying a given factor K to this information d.

More precisely, the second value L_2 of the amount of fluid present in the tank is determined 80 by the calculating unit 14 on the basis of the following formula:

$$L_2(n) = L_2(n-1) - Kd,$$

in which:

- 85 $L_2(n)$ represents the second value L_2 at the moment n,
- $L_2(n-1)$ represents the second value L_2 at the moment (n-1),
- d represents the information delivered by the flowmeter 12, representative of the flow of fluid,
- K represents said factor.

At the step 53, the values L_1 and L_2 determined at the preceding steps 51 and 52 are compared. When the absolute value of the 95 difference between L_1 and L_2 is greater than a given value X, the second value L_2 is reset in step 54, making it equal to the first value L_1 .

Said second value L_2 is then representative of the amount of fluid contained in the tank 10 and this second value L_2 is displayed, in step 55, by the means 17. The method according to the present invention is then resumed before the step 51 in such a manner as to bring said first L_1 and second L_2 values representative of the amount of fluid present in the tank 10 constantly up to date.

Naturally, if the difference between the two values L_1 and L_2 is less than said constant X (step 110 53), the value of L_2 determined directly is displayed by the means 17.

By way of non-limiting example, the value X may be equal to

$$1 + \frac{L_2}{20}$$

Naturally, this value X may be selected differently.

115 Furthermore, as previously indicated, the method according to the present invention consists in modifying the factor K applied to the

information d delivered by the flowmeter 12, for the calculation of said second value L_2 , depending on the difference existing between the first value L_1 and the second value L_2 .

5 According to a first variant, said modification effected on the factor K applied to the information d delivered by the flowmeter 12 is effected as follows:

10 if the first value L_1 is lower than the second value L_2 , the factor K is taken $=\alpha K$ nominal, a relationship in which α is greater than 1 and, for example, $\alpha=1.3$.

15 whereas if the first value L_1 is higher than the second value L_2 , the factor K is taken $=\beta K$ nominal, a relationship in which β is less than 1, for example $\beta=0.7$.

20 Such a smoothing prevents any rise of the second value L_2 and always tends to bring the second value L_2 closer to the first L_1 , on the average. Of course, the values α and β can be easily determined for this purpose.

25 According to a second variant, the modification effected on the factor K applied to the information d delivered by the flowmeter 12 is carried out by taking the factor $K=K$ nominal

$$\frac{L_2 - L_1}{(1 + \frac{L_2 - L_1}{L_2})}$$

a relationship in which:

L_2 represents the second value and

L_1 represents the first value.

30 According to a third variant, the modification effected on the factor K applied to the information d delivered by the flowmeter 12 is carried out by taking the factor $K=K$ nominal

$$\frac{L_2}{L_1}$$

35 a relationship in which:

L_2 represents the second value and

L_1 represents the first value.

Finally, according to a fourth variant, the

40 modification effected on the factor K applied to the information d delivered by the flowmeter 12 is carried out by taking the factor $K=K$ nominal

$$[\bar{T} + f(L_2 - L_1)]$$

a relationship in which:

45 $f(L_2 - L_1)$ represents a function having the difference existing between the second value L_2 and the first value L_1 as a variable.

The contents of the register 16 are taken into account for the display, by the means 17, of the contents of the tank 10 and for the calculation of 50 the cruising range.

In order to avoid the problems associated with the stopping of the engine and the opening of the electric feed circuit, it is possible to envisage transferring the contents of the registers 15 and 55 16 to permanent stores. Nevertheless, it is

possible to provide that, when voltage is again applied to the circuit, the first measurement of L_0 , determined on the basis of the information delivered by the gauge 11, is transferred to the

60 registers 15 and 16, as an initial value of L_1 and L_2 . Such an arrangement renders it possible, in particular, to take into account, in a simple and rapid manner, the sudden variations in the fuel level in the tank 10 which appear, in particular, when said tank 10 is filled.

65 As illustrated in Figure 3, in which the curve L_2 appears, if the gauge 11 is placed at a point where the level varies little with the inclination of the car, even if the fuel level varies with the 70 waves, the display effected by the means 17 is effected with the precision of the gauge 11 and in a continually decreasing manner which is therefore not disturbing to the driver.

75 On the other hand, it appears that the various breakdowns liable to be encountered with the device according to the present invention can be simply traced. This if the level gauge 11 should be cut off, the indication delivered by the display means 17 would oscillate between two values

80 corresponding substantially to the maximum level of the tank 10. Such a phenomenon is due to the fact that at the start, the gauge 11 indicates that the tank 10 is full. This indication is taken into account in the registers 15 and 16. The contents 85 of the register 16 are brought up to date on the basis of the pulses delivered by the flowmeter 12, therefore the information delivered by the display means 17 tend to diminish substantially but is reset to the maximum value as soon as the 90 difference between the registers 15 and 16 exceeds the aforesaid value X . In a similar manner, if the gauge 11 is short-circuited, the display means 17 indicate that the tank 10 is empty. Such a phenomenon is due to the 95 registers 15 and 16 initially taking into account the information "tank empty" delivered by the gauge 11.

100 As illustrated diagrammatically in Figure 4a, when the flowmeter 12 is cut off or short-circuited, the information delivered by the display means 17 decreases in steps. Such a phenomenon is due to the fact that the contents of the register 16 are not continuously brought up to date on the basis of the information delivered 105 by the flowmeter 12, because this is not delivering any pulses. The register 16 is therefore only brought up to date, in steps, when the difference existing between the register 15 and the register 16 exceeds the aforesaid value X .

110 Finally, as apparent in Figure 4b, when the flowmeter 12 delivers too great a number of pulses per cm^3 of fuel withdrawn from the tank 10, the information delivered by the display means 17 appears in the form of saw teeth. Such 115 a phenomenon is due to the fact that the contents of the register 16 are reduced much more rapidly than the contents of the register 15. In such a case, when the difference between the contents of the register 15 and the contents of 120 the register 16 exceeds the aforesaid value X , the

bringing up to date of the register 16 always tends to raise the value of this.

The flowmeter 12 may be replaced by any other suitable means capable of delivering information representative of the amount of fluid or fuel withdrawn from the tank per unit of time. By way of example, the flowmeter 12 could be replaced by an element sensitive to the number of revolutions of the engine or to the admission 10 suction.

Claims

1. A method of measuring the amount of fluid contained in a tank, comprising:
 - (a) measuring the level of the fluid in the tank by means of a gauge,
 - (b) determining a first value $L_1(n)$ related to the amount of fluid present in the tank from a value L_0 representing the fluid level provided at a given moment (n) by the gauge and from a first value $(L_1(n-1))$ previously determined,
 - (c) measuring the amount of fluid withdrawn from the tank per unit of time,
 - (d) determining a second value L_2 related to the amount of fluid present in the tank from the measured flow rate, applying thereto a given factor (K):
 - (e) comparing the values L_1 , L_2 , related to the amount of fluid, as determined in steps (b) and (d);
 - (f) resetting the second value L_2 to equal the first value L_1 , each time the difference between these two values L_1 , L_2 exceeds a given threshold X, said second value (L_2) then representing the amount of fluid;
 - (g) modifying the factor K applied to the measured flow rate for the calculation of said second value (L_2) in the step (d) depending on the difference existing between the first value L_1 and the second value L_2 ; and
 - (h) repeating the steps (a) to (g).
2. A method as claimed in Claim 1, in which for step (c) a flowmeter is used.
3. A method as claimed in Claim 1 or 2, in which said first value L_1 is determined in step (b) 45 according to the equation:

$$L_1(n) = \frac{(p-1)}{p} L_1(n-1) + \frac{L_0}{p}$$

in which:

$L_1(n)$ represents the first value L_1 at the moment (n),

$L_1(n-1)$ represents the first value L_1 at the moment (n-1),

L_0 represents a datum proportional to the value representative of the fluid level delivered by the gauge (11), and

p represents any whole number.

4. A method as claimed in any one of Claims 1 to 3, in which the second value related to the amount of fluid present in the tank is determined according to the equation:

60 $L_2(n) = L_2(n-1) - Kd$,
in which:
 $L_2(n)$ represents the second value L_2 at the moment (n),
 $L_2(n-1)$ represents the second value (L_2) at the moment (n-1), and
 d represents the measured flow rate.

65 5. A method as claimed in Claim 4, in which the modification effected in step (g) of the factor K is carried out as follows:
70 if the first value L_1 is lower than the second value L_2 , the factor K is taken as αK nominal, a relationship in which α is greater than 1,
whereas if the first value L_1 is higher than the second value L_2 , the factor K is taken as βK nominal, a relationship in which β is less than 1.

75 6. A method as claimed in Claim 4, in which the modification effected in step (g) of the factor K is carried out by taking the factor K as K nominal

80
$$(1 + \frac{L_2 - L_1}{L_2})$$
.

7. A method as claimed in Claim 4, in which the modification effected in step (g) of the factor K is carried out by taking the factor K as K nominal.

85
$$\frac{L_2}{L_1}$$
.

8. A method as claimed in Claim 4, in which the modification effected in step (g) of the factor K is carried out by taking the factor K as K nominal

90
$$(1 + f(L_2 - L_1))$$
.

in which

$f(L_2 - L_1)$

is a function of the difference between L_2 and L_1 .

9. A device for carrying out the method as claimed in any one of Claims 1 to 8, comprising a gauge for measuring the level of the fluid contained in the tank, means for measuring the amount of fluid withdrawn from the tank per unit of time, and means for determining a first value $L_1(n)$ related to the amount of fluid present in the tank 10 depending on the information (L_0) representative of the fluid level, weighting this information on the basis of a first value $L_1(n-1)$ previously determined, further for determining a second value related to the amount of fluid present in the tank from the measured flow rate to which is applied said factor K, further for comparing the two values L_1 , L_2 , further for resetting the second value L_2 to equal L_1 when the difference between the values L_1 , L_2 exceeds

a given threshold, and for modifying the factor K depending on the difference existing between the first and second values L_1 and L_2 .

5 10. A device as claimed in Claim 9, in which said means for measuring the amount of fluid withdrawn from the tank is a flowmeter.

11. A device as claimed in Claim 9 or 10, comprising means for storing the first and second values L_1 , L_2 and means for displaying the second 10 value L_2 to represent the amount of fuel present in the tank.

12. A device as claimed in any one of Claims 9 to 11, in which said means for determining said first value L_1 is arranged to calculate the value

$$15 \quad L_1(n) = \frac{(p-1)}{p} L_1(n-1) + \frac{L_0}{p}.$$

in which:

$L_1(n)$ represents the first value L_1 at the moment (n),

$L_1(n-1)$ represents the first value L_1 at the moment (n-1),

L_0 represents a datum proportional to the information representative of the level of fluid delivered by the gauge (11), and p represents any whole number.

20 25 13. A method as claimed in claim 1 and substantially as herein described, for measuring the amount of fluid contained in a tank.

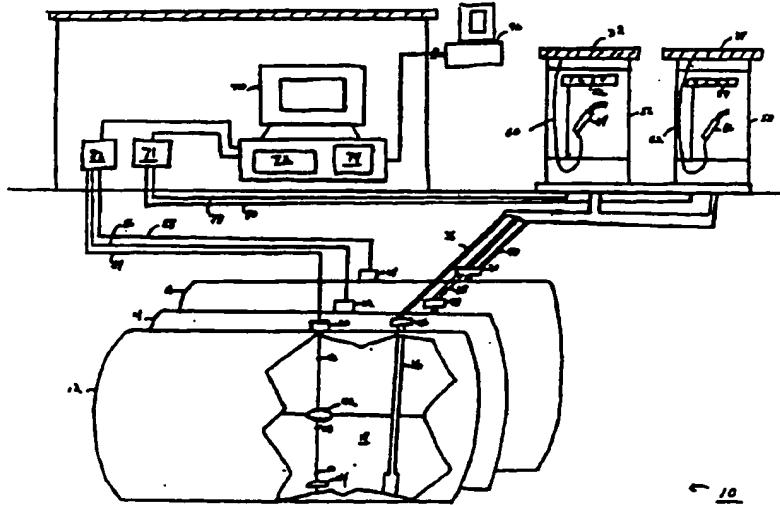

14. A device for measuring the amount of fluid contained in a tank, which device is substantially 30 as herein described with reference to the accompanying drawings.

(54) Title: METHOD AND APPARATUS FOR MONITORING OPERATIONAL PERFORMANCE OF FLUID STORAGE SYSTEMS

(57) Abstract

The operational performance of a fluid storage (12, 14, 16) and dispensing system (32, 34) is monitored by measurement apparatus which measures a volume associated with the system. A plurality of measurement data is collected from the measurement apparatus in a form readable by a computer (70, 90) and is stored in a compressed matrix format in a computer memory (74). The compressed matrix format is statistically analyzed to determine operational monitoring information regarding the system. The temperature of the fluid may be measured for calculating the volume (18) associated with the system. The operational performance and volume of the fluid storage system (12, 14, 16) may be precisely monitored without requiring presumptions as to the accuracy of the measurement apparatus (82).

METHOD AND APPARATUS FOR MONITORING
OPERATIONAL PERFORMANCE OF FLUID STORAGE SYSTEMS

Background of the Invention

5 The invention relates to monitoring the operational performance of fluid storage systems. Large quantities of liquids and similar materials are often stored in bulk storage containers or tanks, which may be located above-ground, partially above-
10 ground, or completely below ground. Such containers or tanks are generally connected by piping to flow-meters or dispensers.

For example, underground storage tanks (UST's) and, occasionally, above-ground storage tanks (AST's) are
15 used to store petroleum products and fuel to be dispensed at automobile service stations, trucking terminals, automobile rental outlets, and similar operations through gasoline, diesel, or kerosene dispensing pumps. Fuel product is generally delivered to such facilities by a
20 gravity drop from a compartment in a wheeled transport means such as a fuel delivery truck. AST's or UST's are often located at central distribution locations so that product can be subsequently withdrawn from the tank system to be transported for delivery to a variety of
25 such facilities. A distribution location with UST's or AST's may receive deliveries of product from, e.g., a pipeline spur, wheeled transport, a barge, or a rail car.

Direct observation of the operating condition of such tanks and storage containers is difficult or
30 impossible. The various methods for identifying the amount of product in tank systems have varying levels of accuracy, repeatability, and performance. Moreover, the accuracy of devices which measure the amount of product dispensed from the storage containers and tanks differs
35 greatly, and may or may not be temperature compensated.

- 2 -

The amount of product actually delivered to the tank system is often measured inaccurately and, frequently, not at all. Rather, the owner or operator of the tank or vessel usually records the invoiced amount of product 5 delivered as the actual amount introduced to the tank system, without having any means of confirming whether the invoiced amount of product delivered is correct.

Consequently, effective management of such facilities is complicated by the numerous errors in the 10 various measuring devices and procedures used to establish a baseline for management, planning and decisionmaking. Effective management requires the following:

1. Accurate measurement of the volume stored in the 15 system.
2. Accurate determination of the volume dispensed from the system.
3. Accurate determination of the amount of product introduced into the system.
- 20 4. Identification of volumes added to or removed from the tank system which are not otherwise recorded.
5. Rapid identification of leakage from the tank system.
6. Continuous monitoring and diagnosis of the 25 operating performance of all of the component measuring devices of the system.
7. Continuous analysis of sales data to predict demands of product from the system.
8. Determination of optimal reorder times and 30 quantities as a function of ordering, transportation, holding, and penalty costs in order to minimize total costs of operation and/or to maximize profits.

Traditionally, these functions were performed 35 crudely or, in many cases, not at all. Volume

- 3 -

measurements were, and in many instances still are, based on imperfect knowledge of the geometry, dimensions, and configuration of the storage vessel. Also, dispensing meters are frequently miscalibrated. This is true even 5 when tank systems are regulated, due to the breadth of tolerance permitted for individual sales as related to total tank volume. For example, deliveries from the delivery vehicle are almost always unmetered, additions of product from defueling vehicles are typically 10 undocumented, and theft of the product is not uncommon.

Leakage of product has, in recent years, assumed a dimension far in excess of the mere loss of the product. Environmental damage can, and frequently does, expose the operator to very large liabilities from third party 15 litigation in addition to U.S. Environmental Protection Agency (EPA)-mandated remediation which can cost in the range of hundreds of thousands of dollars. The EPA's requirements for leak detection are set forth in EPA Pub. No. 510-K-95-003, Straight Talk On Tanks: Leak Detection 20 Methods For Petroleum Underground Storage Tanks and Piping (July 1991), which is incorporated herein by reference.

To address these concerns, Statistical Inventory Reconciliation (SIR) was developed. The SIR method 25 consists of a computer-based procedure which identifies all of the sources of error noted above by statistical analysis of the various and unique patterns that are introduced into the inventory data and, in particular, into the cumulative variances in the data when viewed as 30 functions of product height, sales volumes, and time.

- 4 -

Summary of the Invention

The present invention relates to an automatic SIR system that may continuously and automatically collect data from completely above-ground, partially above-ground, and completely below ground containers for statistical analysis. The invention addresses a variety of physical, business, operational and environmental issues associated with the bulk storage of liquids or pourable solids.

10 The present invention is an application of SIR that greatly enhances the ability to manage a facility effectively. It provides the means to characterize exactly the geometry, dimensions, and configuration of the storage vessel, identify overages and shortages in 15 deliveries and unexplained additions and removals of product, and provide an accurate assessment of overall dispensing meter calibration. In addition, by accounting for such discrepancies, the present invention permits identification of leakage at rates less than .1 gallon 20 per hour in all of its estimates to any prescribed tolerance. By increasing the number of measurements taken, the estimates can be derived at any desired level of tolerance.

25 The method of the present invention makes no assumptions as to the precision of any of the measuring devices used in various system configurations. Precision and calibration accuracies are derived from the data alone. Also, it is not assumed that the tank system is leak free; the leak status of the system is determined 30 from the data alone.

The method derives tank geometry, dimensions, and configuration, and their impact on the totality of cumulative inventory variances, as a function of product height in the tank. Correctness of dispensing meter 35 calibration is verified in a similar manner by testing

- 5 -

for randomness of cumulative variances as a function of varying sales volumes. Having confirmed that such remaining residual variances are random, reflecting only the inherent random noise of the measurement devices, the 5 present method analyzes departures of the cumulative variance from the bounds determined by the calculated random noise level. All calculations as to the volumes added, removed, metered or leaking are based upon extended successive, simultaneous observations of meter 10 and gauge readings. The number of observations incorporated in each such calculation is determined by computing confidence bands for the parameters of interest and extending data collection as necessary to achieve predetermined tolerances.

15 For example, the method of the present invention is capable of distinguishing between continuous losses consistent with leakage and one-time unexplained removals of the fluid product from the tank. The method may be used to ensure the accuracy of computed delivery volumes, 20 which are determined and reported with confidence boundaries calculated for estimated delivered quantities.

The method can also be used to control and monitor the accuracy of purchase costs of fluids such as petroleum which are delivered to tanks. For example, 25 motor fuel retailers may be charged by wholesalers for either net or gross volumes purported to have been delivered. A determination that purchase charges are appropriate thus requires frequent simultaneous readings of sales, tank volumes and temperatures, which can be 30 accomplished using the method of the present invention.

To accomplish these goals, the present invention involves estimating changes in product volume in a tank based on multiple data points and their respective likely errors measured continuously over a period of time. A 35 software program is used to implement an algorithm that

- 6 -

employs concepts from matrix theory and mathematical statistics. The algorithm includes generating the product of a matrix and its transpose by successive additions of partial products of partitions of the matrix 5 and their corresponding transposed matrix partitions to minimize the storage requirements of the data collected. The compressed matrix data constitutes a complete and sufficient statistic for the parameters of interest. The algorithm thus permits the accumulation and storage of a 10 large amount of data in a condensed form without sacrificing statistically useful information, to obtain a statistically significant result with the required accuracy and reliability.

Thus, one object of the present invention is to 15 determine the accuracy and consistency of devices used to measure volume of product added to, removed from, and present in a fluid storage system.

Another object of the invention is to identify and 20 quantify additions of material to the system, but not recorded as such, and volumes of product removed from the 25 system which are not registered by measuring devices or otherwise recorded.

Another object of the invention is to discriminate 25 between discrete one-time unrecorded removals of product from the system and continuous losses consistent with leakage.

Another object of the invention is to identify and 30 provide early warning of product leakage from all parts of the system, extending from the fill point to the point of discharge, and to confirm the validity of resulting leakage warnings.

Another object of the invention is to determine 30 secular, seasonal trends and repetitive special demands to provide short and long term estimates for demand of

- 7 -

the product, and to provide optimal reorder quantities and a delivery schedule for the system.

A further object of this invention is to accomplish all of the foregoing in a fully automated system that requires no human intervention, other than as an option available to the operator to enter quantities of material reportedly delivered for comparison with those computed.

In general, in one aspect, the invention features 10 a method of monitoring a fluid storage and dispensing system. The system has measurement apparatus for measuring a volume associated with the system. A plurality of measurement data is collected from the measurement apparatus in a form readable by a computer 15 and stored in a compressed matrix format in a computer memory. The compressed matrix format is statistically analyzed to determine operational monitoring information.

Implementation of the invention also may include one or more of the following features. The statistically 20 analyzing step includes calculating error data resulting from the measurement apparatus. The method may also include determining the presence of operational defects in the system, monitoring the accuracy of the measurement apparatus, determining the volume of fluid in the system, 25 and determining whether a quantity of fluid removed from the system is caused by a leak in the system. The method also may include delivering a warning that a leak has been detected in the system.

The collecting step may be performed while the 30 system is operating, may be performed continuously at periodic intervals, and may be performed automatically under the control of the computer. The method may include querying the measurement apparatus under the control of the computer.

- 8 -

The method may include measuring the temperature of the fluid and calculating the volume based on the temperature of the volume in the system. The calculating step may include determining a correction value based on 5 a weighted average of the temperature of the volume measured at a plurality of locations within the system.

The system may include a plurality of tanks, including an underground storage tank, an above-ground storage tank, or a partially above-ground storage tank.

10 The storing step may include generating the compressed matrix format as a product of a data matrix and the transpose of the data matrix. Further, the product may be formed by addition of partial products of each of a plurality of partitions of the data matrix with 15 the transpose of each of the partitions.

The measurement apparatus may include a volumetric gauge, a dispensing apparatus and a sales recording device. The measurement data or the compressed matrix format may be transmitted to a host processor to perform 20 the statistical analysis. The collecting step also may include estimating an initial volume of fluid in the system.

In general, in another aspect, the invention features a method of monitoring a fluid storage and 25 dispensing system. The system includes measurement apparatus for measuring a volume associated with the system. A plurality of measurement data is collected from the measurement apparatus in a form readable by a computer and stored in a compressed matrix format in a 30 computer memory. The compressed matrix format is statistically analyzed, to determine whether a quantity of fluid removed from the system is caused by a leak in the system. A warning that a leak has been detected in the system is delivered.

- 9 -

In general, in another aspect, the invention features an apparatus for monitoring a fluid storage and dispensing system. Measurement apparatus measure a volume associated with the system. A computer includes a 5 processing means for collecting a plurality of measurement data from the measurement apparatus and a memory for storing the plurality of measurement data in a compressed matrix format. The processing means performs statistical analysis of the compressed matrix format to 10 determine operational monitoring information.

Implementation of the invention also may include one or more of the following features. The system may include a plurality of tanks, including an underground storage tank, an above-ground storage tank, or a 15 partially above-ground storage tank.

The measurement apparatus may include a volumetric gauge, a dispensing apparatus and a sales recording device. The volumetric gauge may include a probe disposed in the system, and the probe may be a 20 magnetostrictive tank probe. The dispensing apparatus may include a totalizer. The sales recording device may simulate operation of a point of sale terminal. Also, the measurement data may be collected simultaneously from the various measurement apparatus.

25 The system may include a temperature sensor disposed in the system in contact with the volume for obtaining a temperature measurement in the volume. Alternately, the system may include a plurality of temperature sensors disposed at different locations 30 within the system, each of the sensors being in contact with the volume for obtaining a plurality of temperature measurements of the volume. The temperature measurements may be used to calculate the volume.

35 The measurement data obtained from the measurement apparatus may be transmitted to the computer. A host

- 10 -

processor remote from the computer may perform the statistical analysis.

The compressed matrix format may be generated as a product of a data matrix and the transpose of the data 5 matrix. Further, the product may be formed by addition of partial products of each of a plurality of partitions of the data matrix with the transpose of each of the partitions.

In general, in another aspect, the invention 10 features a method of monitoring a fluid storage and dispensing system. The system has a plurality of measurement apparatus for measuring a volume associated with the system. Measurement data is simultaneously collected from the plurality of measurement apparatus in 15 a form readable by a computer to determine a change in the volume. The collecting step is repeated to obtain a plurality of measurement data from the plurality of measurement apparatus. The plurality of measurement data is stored in a compressed matrix format in a computer 20 memory, and the compressed matrix format is statistically analyzed to determine operational monitoring information.

Implementation of the invention may also include the following feature. The method may include estimating an initial value of the volume during the analyzing step.

25 In general, in another aspect, the invention features a method of monitoring a fluid storage and dispensing system. The system has measurement apparatus for measuring a volume associated with the system and a plurality of temperature sensing devices located at 30 different heights in the system. The volume has a height in the system. A plurality of volume measurement data is collected from the measurement apparatus in a form readable by a computer. The volume measurement data is adjusted based on temperature measurements taken from 35 those of the plurality of temperature sensing devices at

- 11 -

a height below the height of the volume in the system. The plurality of volume measurement data is stored in a compressed matrix format in a computer memory, and the compressed matrix format is statistically analyzed to 5 determine operational monitoring information.

In general, in another aspect, the invention features a method of determining a volume associated with a fluid storage and dispensing system. The volume has a height in the system, and the system has measurement 10 apparatus for measuring the height. A plurality of height measurement data is collected from the measurement apparatus in a form readable by a computer. The plurality of height measurement data is stored in a compressed matrix format in a computer memory. 15 Regression analysis is performed using the compressed matrix format to calculate the volume associated with the system.

Implementation of the invention may also include one or more of the following features. The collecting 20 step may be performed each time a portion of the volume is dispensed from the system. The collecting step may not be performed when the fluid is being added to the system.

In general, in another aspect, the invention 25 features an apparatus for determining a volume associated with a fluid storage and dispensing system. The volume has a height in the system, and measurement apparatus measures the height of the volume. A computer has a processing means for collecting a plurality of height 30 measurement data from the measurement apparatus and a memory for storing the plurality of height measurement data in a compressed matrix format. The processing means performs regression analysis of the compressed matrix format to determine the volume associated with the 35 system.

- 12 -

In general, in another aspect, the invention features a method of determining a plurality of volumes, each of the volumes associated with one of a plurality of fluid storage and dispensing systems. Each of the 5 volumes has a height in its associated system, and each of the systems has measurement apparatus for measuring the height for each of the volumes. A plurality of height measurement data is collected from the measurement apparatus of each of the plurality of systems in a form 10 readable by a computer. The plurality of height measurement data is stored in a compressed matrix format in a computer memory. Regression analysis is performed using the compressed matrix format to calculate the volumes associated with the systems.

15 Other features and advantages of the invention will become apparent from the following detailed description, and from the claims.

Brief Description of the Drawings

5 Description of the Preferred Embodiments

The method and apparatus described herein applies to UST's, AST's or any type of storage tank. The product stored in the tank may be any fluid, including dry particles that flow in the manner of a fluid.

10 Fig. 1 shows a UST facility 10, illustrated as an automobile service station. Facility 10 includes a series of UST's 12, 14, 16 which may store the same or different types of liquid fuel product 18. Volumetric tank gauges 20, 22, 24 in each tank measure the height of 15 product 18 in the tank. Submersible pumps 26, 28, 30 in each tank pump product 18 to one of dispensing pumps 32, 34 through piping lines 36, 38, 40. Alternately, facility 10 may be an AST facility with above-ground tank 1000, as shown in Fig. 11, or a facility with a partially 20 above-ground tank 1010, as shown in Fig. 12.

Tank gauges 20, 22, 24 are mounted in tanks 12, 14, 16. The tank gauges may consist of or be based on magnetostrictive tank probes or other sensing technologies. In the case of magnetostrictive 25 technology, two floats 42, 44 surround each probe, e.g., gauge 20 in tank 12. One float 42 floats on the upper surface of product 18 in tank 12, and the other float 44 floats on the interface of product 18 with any water or other foreign material collected at the bottom of tank 30 12. Tank gauge 20 determines the distance between floats 42, 44 to obtain the height of product 18 in tank 12. Tank gauge 20 also contains temperature sensors 46, 48, 50 spaced along its length to monitor the temperature of product 18 at various depth levels.

- 14 -

Each of the dispensing pumps 32, 34 consists of a totalizer or flow meter 52, 54 disposed in a housing 56, 58 to measure the volume of product 18 dispensed through hoses 60, 62 and nozzles 64, 66. To operate dispensing 5 pump 32, nozzle 64 is removed from housing 56, which actuates dispensing pump 32 and causes product 18 to flow through hose 60 due to the pumping action of submersible pumps 26, 28, 30. A value stored in totalizer 52 is incremented as fuel is dispensed through hose 60. Upon 10 completion of the transaction, nozzle 64 is replaced in housing 56, thereby turning off dispensing pump 32 and discontinuing the action of submersible pumps 26, 28, 30 and totalizer 52.

Transactions are recorded electronically by 15 software in a sales recording device 71 connected to totalizers 52, 54 of dispensing pumps 32, 34. Totalizers 52, 54 in dispensing pumps 32, 34 are connected to sales recording device 71 by means of communications and power supply wires 78, 80.

20 Sales recording device 71 contains software capable of emulating the functions of a point of sale (POS) terminal associated with fuel sales made at facility 10. POS emulation software in sales recording device 71 functions on the basis of read only commands to 25 eliminate the possibility of conflict with control commands from a POS terminal employed by facility 10. Alternative data acquisition systems can result in destruction of credit card sales records, inadvertently shutting down the entire system, and/or causing 30 electrical interference in the pump links.

Tank gauges 20, 22, 24 are connected to a tank monitor 82 by means of communications and power supply wires 84, 86, 88 or communicate data through radio frequency transmission. Tank monitor 82 converts raw

- 15 -

data obtained from tank gauges 20, 22, 24 into a form usable by a computer.

A computer 70 contains a processor 72 capable of running various computer software applications and a 5 memory 74. Tank monitor 82 and sales recording device 71 are electrically connected to computer 70 to relay totalizer values, product height and temperature data to computer 70. Software executable by processor 72 of computer 70 is capable of querying tank monitor 82 and 10 sales recording device 71 to obtain measurement data at selected time intervals. The data is continuously evaluated as it is collected and is stored in memory 74 of computer 70 for later retrieval and detailed analysis. Alternatively, computer 70 may communicate with a host 15 processor 90 at a remote location. The continuous evaluations or detailed analysis may then be performed by host processor 90, which may be faster or more efficient than computer 70.

As an example, computer 70 may be a personal 20 computer or any other proprietary microprocessor-based unit. Computer 70 may capture data automatically through direct-connect serial interfaces with tank monitor 82 and sales recording device 71, or by manual operator keypad entry. Computer 70 communicates with equipment at 25 facility 10 through four programmable serial communication ports, such as RS-232 communication ports.

Computer 70 may, e.g., store tank dimensions and product characteristics, and concurrent time and date data along with the measurement data. Computer 70 may be 30 used to produce error and analysis reports as calculated by the software. It may also have alarm event-initiated capabilities, such as when a leak is detected in any of the tanks. Such a computer system can accommodate facility and customer specific requirements while

- 16 -

maintaining complete compatibility with other system components.

The SIR method involves reconciling volume data obtained from tank monitor 82 and volume data obtained 5 from sales records. Sales transactions may be detected in a number of ways, including an electronic signal emitted from totalizers 52, 54, by voltage sensing of control relays on pump dispensers 32, 34, or by observation of product removal using tank gauges 20, 22, 10 24.

It is essential that the measurements used to obtain these two types of data are made simultaneously. The SIR method of the present invention collects and analyzes observations of sales volumes and tank volumes 15 which are derived simultaneously. Failure to collect both types of data simultaneously would bias estimates derived from separate volume measurements.

The SIR method properly accounts for the effects of temperature, pressure and specific gravity. In 20 addition, product from two or more tanks may be blended, such as to achieve varying petroleum octane levels at pump dispensers 32, 34. When different fluid products are blended, the tanks are treated as one unit, and an additional parameter is introduced to determine the 25 actual blend percentages.

Data concerning the physical characteristics of the tank configurations and the accuracy of the various gauges and metering devices is collected during installation and a set-up phase of operation of facility 30 10 to create a basis for subsequent statistical analysis. Information is then continuously collected so that the statistical analysis of SIR can be performed by computer 70 or host processor 90.

Several procedures are used either singly or in 35 combination to obtain the volume observations. First,

- 17 -

where the system configuration provides for determining whether hoses and dispensers associated with a given tank are active, the system is queried on a minute-by-minute basis, or on the basis of another predetermined time 5 interval, to determine the status of the dispensers. When all of the dispensers are idle, the values from totalizers 52, 54, the tank volumes (i.e. product heights in the tanks) and temperatures are recorded.

Second, submersible pumps 26, 28, 30 are checked 10 to determine on/off status. When it is determined that the pumps are turned off, the values from totalizers 52, 54 are read, and tank volumes and temperatures are recorded.

Third, software algorithms used by computer 70 15 detect and measure leads and/or lags between the recording of sales events and corresponding gauge and meter readings. When leads or lags are encountered and constitute a physical characteristic of the data measurement and recording system, constrained 20 optimization, rather than unconstrained optimization, may be used to determine parameter estimates. Lagrange multipliers are one example of such a constrained optimization method.

The method of the present invention is capable of 25 providing dynamic monitoring of system performance. For example, the leak detection function is carried out continuously while normal operations, e.g., removals and deliveries, are taking place. To detect leaks dynamically, the software is programmed to detect when 30 sales or delivery events occur and to calculate the volumes of product removed or added as a result of such activities. Thus, dynamic testing does not require that the system be dormant and addresses the entire system from the point of filling to the point of dispensing.

- 18 -

The SIR method of the present invention also distinguishes between one-time removals and continuous losses consistent with leakage. The integrity or leak-free status of the system is not assumed a priori.

5 Instead, the individual and unique characteristic pattern induced by each form of error when viewed along the separate dimensions of time, product height and sales volume are used to identify and quantify the errors. The method may also be used to detect and quantify
10 undocumented removals, e.g., theft or additions of product.

Further, the overall system is self diagnosing in that it determines from the data the maximum degrees of reliability and precision of which a particular operating
15 configuration is capable at any given time, as well as the degree of calibration accuracy.

In particular, product height in the tanks and temperature are measured continuously at, e.g., one-minute intervals. Height and gross volumes are converted
20 to net volumes at, e.g., 60°F or 15°C, using the algorithms described below. Sales recorded by the totalizers 52, 54 are extracted and stored in memory 74 at times coincident with readings from tank gauges 20, 22, 24. If the dispensing system is capable of
25 transmitting a signal indicating whether or not any or all individual hoses are active, that information is also stored in memory 74 coincident with taking gauge and meter readings.

The method of the present invention is designed to
30 achieve the maximum accuracy possible within the limitations imposed by the inherent random and irreducible noise in the various measuring devices incorporated. It utilizes multiple measurements over extended time periods to identify and quantify systematic
35 and repeatable effects in the instrumentation and thereby

- 19 -

correct for such effects using the known physical characteristics of the devices. The system makes no a priori assumptions as to the accuracy of the devices used to measure product volume in the tank, to measure volumes removed, or as to the accuracy of volumes reported to have been delivered into the system.

The resulting volumetric calculations are independent of the physical characteristics of the tank configuration and the various measuring devices which may 10 be incorporated in the system. The results do not rely on input entered externally by the operator or from diagnostics internal to the measuring devices used. Instead, the output produced by the software which analyzes the measured data depends only the patterns 15 induced in inventory data produced by the tank gauges and measuring devices and, in particular, the cumulative variances that result when the various input values are combined.

Various error patterns which the measuring devices 20 can induce and the effects of temperature, tank geometry, and orientation on cumulative variances are derived from empirical analysis of real-world inventory data. The system's software synthesizes the output measurements of the various devices based on known characteristics 25 derived from the empirical data. Thus, the software is capable of identifying measurement errors caused by the measuring devices and simultaneously compensating for the effects of those errors.

Gauges can be systematically inaccurate in two 30 ways. The height of the product in the tank can be incorrect, and the height to volume conversion algorithms may not reflect accurately the true dimensions of the tank or its orientation in the ground. The latter may be the result of incorrect measurements or an inappropriate 35 conversion algorithm.

- 20 -

The presence of such systematic effects and their nature may be established by examining the pattern of inventory variances as a function of product height. Errors of this kind induce patterns which repeat 5 themselves as the tank is filled and emptied. If the tank length is incorrect, a linear pattern is induced. If product height is in error, a curvilinear pattern results reflecting the varying volumes in different cross sections of a cylindrical tank. Tilt along the length of 10 the tank induces a sinusoidal pattern symmetrical about the mid-height of the tank. Absent such errors, the pattern will be purely random, reflecting only the inherent noise of the measuring devices. The absence of randomness and the presence of a systematic pattern 15 serves to identify the presence of systematic error. The pattern of a departure from random and its extent determines the source and extent of the effects and the means necessary to correct them.

Dispensing errors, unlike volume measuring errors, 20 are independent of product height, but are sensitive to the volume of product dispensed. The nature and extent of dispensing errors can be established by examining inventory variances as a function of sales volume. As in the case of volume measurements, in the absence of 25 systematic errors, variances as a function of sales volume will be random. The form and extent of departures from randomness serve to determine the source and extent of the errors and provide for their removal.

Leakage from the system creates a continuous 30 downward trend in the cumulative variance when viewed as a function of time. By contrast, one-time additions and removals of product cause significant upward or downward translations of the cumulative variance which remain 35 permanently in the record and do not introduce a continuous trend. Leakage is distinguishable from tank

- 21 -

gauging errors when viewed as a function of product height because the pattern does not repeat as the tank is filled and emptied. If product is leaking from the system, a series of parallel translations in the 5 cumulative variance is generated, each shifted by the volume of product lost between deliveries.

The accuracy of measurements taken from the various components of the system determines the accuracy achievable in any one individual observation. Since the 10 leak rate is computed from a series of successive observations, however, the minimum detectable leak rate can be reduced to any desired magnitude by increasing the number of successive observations recorded. Thus, the 15 system can serve as a final verification for leakage indications obtained by other methods.

At the conclusion of an initial set up period of data collection including one or more delivery and sales cycles, the collected measurement data is analyzed by regression analysis. The initial set-up regression is 20 used to derive tank dimensions and orientation, individual meter calibrations and secular trends. A confidence level value p is computed at the .01 level of significance to determine the minimum leak rate detectable by the system, and the residual variance is 25 computed to provide the current noise level of the system.

The regression is performed according to the following equation:

$$st_i(R, L, T) = a - \sum_{j=1}^J \sum_{k=1}^K \alpha_k S a_{kj} + \sum_{j=1}^J D_j - Et_i Ls + \sum_{j=1}^J B_j I_{ij} \quad (1)$$

where:

30 $st_i(R, L, T)$ = Volume in gallons derived from the i th gauge reading in inches in a cylindrical tank with or without hemispherical end

- 22 -

caps with radius R, length L, and tilt over its length of T inches.

a = Initial inventory in gallons, which is to be estimated.

5 Sa_{kj} = Sales volume recorded on the k th totalizer.

a_k = Fraction of sales volume recorded on the k th totalizer actually removed from the tank, which is to be estimated.

10 D_j = Volume of the j th delivery.

Et_i = Elapsed time since initiation until the i th gauge reading is recorded.

Ls = Constant gain or loss in product per unit of time.

15 B_j = Volume of product added (e.g. delivery) or removed during some discrete time interval prior to or during observation period j .

$$I_{ij} = \begin{cases} 0 & \text{if } j < i \\ 1 & \text{if } j \geq i \end{cases}$$

All of the parameters are estimated simultaneously using least square estimation procedures. The R and T parameters are derived numerically, but the other parameters are derived analytically.

Further, all of the parameters, including the initial inventory, are estimated simultaneously. The initial volume must be estimated from all succeeding data, even if the tank is initially empty, otherwise the initial gauge reading and its conversion to gallons is assigned a credibility not assumed for all succeeding readings. Also, in a great majority of applications, the initial inventory in an already existing and operating system is not accurately known.

Initial inventory estimation is vital in determining the geometry of the tank. When tank

- 23 -

geometry, tank orientation, or tank product height measurement depart from the values obtained from nominal sources, all gauge and meter measurements are affected. It is practically impossible to detect the errors induced 5 in the gauge measurements and correct for them unless the estimation of the initial inventory is made coincident with the estimation of the values of the other parameters.

The estimate of the parameters are based on the 10 totality of the data collected. This means, e.g., that the estimate of leak rate L_s is determined from a linear trend including all of the data collected, not merely at one end of the reconciliation period. Likewise, estimates of tank dimensions and orientation are derived 15 from their overall contribution to reduction in residual variance, as opposed to a sale by sale analysis of tank segments.

The volume $st_1(R, L, T)$ is derived from the product height measurement by multiplying the constant area of 20 tank segments of height h (in inches) by tank length L . The volume in gallons of product in a horizontal cylindrical tank of radius R is given by:

$$Vol = \frac{L}{231} \left[R^2 \cos^{-1} \left(\frac{R-h}{R} \right) - (R-h)(2Rh - h^2)^{\frac{1}{2}} \right]$$

In the case of a tilted tank, the area of the segments vary with position along the length of the 25 tilted tank, and the volume is determined by integrating over the length L . Such integration does not result in a closed form because the cross sections are not circular, and a numerical integration would severely limit the frequency of observations. Instead, in this application

- 24 -

the tank is treated as lying horizontally and the product is considered tilted, to derive an equivalent volume. This integration yields the closed form:

$$Vol = \frac{R^3}{231} \left[(z - 1) \sin^{-1} (2z - z^2)^{\frac{1}{2}} - \frac{1}{3} (2z - z^2)^{\frac{3}{2}} \right] \frac{hu}{R} \frac{h_1}{R}$$

The integrand is evaluated between the normalized product 5 heights in inches, hu/R and h_1/R , at the lower and higher ends of the tilted tank, respectively. It is standard industry practice to install tanks on an incline to divert water and sludge away from the submersible pumps.

Tank tilt is identified from the pattern it 10 induces in the record of cumulative variances as a function of product height. It is compensated for by fitting the correct mathematical form for height to volume conversions in a tilted tank to the cumulative variance calculated by the method of least squares. This 15 is done simultaneously with estimation of the initial inventory.

Tank length L and radius R are established by equating the first partial derivatives of the sum of squared cumulative variance with respect to length and 20 radius and determining the values which minimize the sum of squared variances. Simultaneous estimation of initial inventory is also required when estimating tank length L and radius R.

Errors in measurement of the product height h in 25 the tank are characterized by curvilinear patterns induced by height to volume conversions in the cumulative variance for a cylindrical container when heights are transposed upward or downward. Such errors also are compensated for by minimizing the sum of squared 30 cumulative variances with respect to increments or decrements to measured product height. This estimation

- 25 -

also requires simultaneous estimation of the initial inventory of the tank.

In general, the accuracy of the estimates of the tank dimensions, tank orientation and height measurements 5 is confirmed by observing that the cumulative variances of each derived value as a function of nominal product height are random and display no systematic influence or effects.

Dispenser totalizer calibration is continuously 10 monitored and evaluated by minimizing the sum of squared cumulative variances with respect to multiplicative constants associated with individual reported cumulative sales volumes from all pump dispensers associated with a particular tank system. This eliminates the need for 15 manual verification of meter calibration.

In particular, gauge performance is continuously monitored to identify gauge malfunctions or degradation in gauge performance. Monitoring of gauge performance is independent of diagnostics which are internal to the 20 measuring device. Diagnoses of problems are based only on their impact on the cumulative inventory variances which are continuously monitored by the software.

If the gauge fails to record changes in product height when the dispensers register sales, an increase in 25 cumulative variances approximately equal to sales volume is observed; this effect can be identified by the monitoring software and a warning of gauge malfunction generated to the operator.

However, observation of the gauge registering 30 product height change, but with a time lag after sales are recorded, may be a feature of normal gauge performance. Such normal gauge performance is identified by repeated positive increments in cumulative variances as sales are completed with subsequent return of the 35 cumulative variance to normal bounds. When such gauge

- 26 -

function is determined to be the normal operating characteristic of a particular system, constrained optimization with lagged variables is introduced into the software. Otherwise, the gauge's performance is reported as a malfunction.

Finally, temperatures in the tank are monitored to detect changes that are excessive for the time intervals between observations. Erratic temperature readings are deleted, and may indicate gauge malfunction.

10 The software computes actual, rather than nominal, delivered quantities and requires no input by the system operator. The operator may choose to input into the system the nominal delivery quantity indicated by the delivery invoice, along with the temperature and
15 coefficient of expansion of the product at the point of pick-up. The software will then compute overages or shortages between the nominal and actual quantities delivered, as well as the overages or shortages caused by temperature-induced variations in the transport of the
20 product to the facility and in the subsequent mixing of the delivered product with that resident in the tank.

Delivery is identified by the software when a positive cumulative variance is observed which exceeds the system noise level and is not succeeded by a return
25 to normal variance bounds. Delivered quantities are computed by estimating the volume increases they induce in multiple, successive observations. The required number of successive observations is determined as that sufficient to generate a confidence width which is within
30 a predetermined tolerance. The system of the present invention is capable of accounting for sales conducted during delivery and for noise introduced by post delivery turbulence in the tank.

One-time unaccounted for removals or additions to
35 the tank are computed in the same manner. Deliveries are

- 27 -

distinguished from such events by computing the rate of input, which in the case of normal gravity delivery should exceed 100 gallons per minute. Other modes of delivery, e.g. pipeline delivery into above ground tanks, 5 are identified by incorporating their known delivery rates.

Leakage from the system is identified by a continuous linear negative trend in the data which exceeds the computed minimum detectable leak rate after 10 all of the various error phenomena described above have been identified and compensated for. This calculation deals with the totality of the data obtained by constantly monitoring known removals and is not restricted to observations made only when the system is 15 dormant. It is also independent of any single data reconciliation calculation in that trends throughout all of the data are evaluated.

All calculations concerning volumes are made on the basis of net volumes, according to the following 20 definitions:

$$\text{Net Volume in Tank} = \text{Gauge Volume} (1 - (t-60)CE)$$

where:

25 t = Measured temperature in degrees Fahrenheit (if centigrade, the term in parentheses becomes $(t-15)$).

CE = Coefficient of expansion.

and

$$30 \text{Net Sales Volume} = \text{Metered Sale} (1 - (\frac{t_1 + t_2}{2} - 60) CE)$$

where t_1 and t_2 are temperatures measured by the tank gauge at the beginning and ending of a sale transaction, respectively. Deliveries are computed in net gallons,

- 28 -

but are converted to gross quantities if required, based on external information input by the system operator, as follows:

5 GT = Gross gallons on invoice at the originating terminal.
 NT = Net gallons on invoice at the terminal.
 tT = Temperature at the terminal.
 CE = Coefficient of expansion.

The program also records:

10 t_A = Ambient temperature in the tank prior to delivery.
 t_F = Temperature in the tank at the conclusion of delivery.

The following value is computed:

15 **ts** = Temperature of the product in the
 delivery vehicle at the facility at the
 beginning of delivery.

 = $t_F + \frac{NVA}{NVD} (t_F - t_A)$

20 where:

NVD = Actual net volume delivered, previously computed.

NVA = Net volume in the storage tank at the start of delivery.

25 NS = Net overage(+) (underage (-)) in delivery.

= NT-NVD

GVD = Gross volume delivered.

= NVD (1 ± (tF = 60) CE)

= Cross volume in the tank

- 29 -

GSM = Shrinkage due to mixing in the tank.
= GVS - GVD
GVT = Actual gross volume in the transport vehicle at the facility.
5 = NVD (1 + (tT - 60) CE)
GST = Shrinkage during transit to the facility.
= GVT - GVS
10 GOS = Gross overage(+) (underage(-)) adjusted for temperature effects
= GT - GVD + GST + GSM

Calculations of volumes actually delivered are based on multiple observations of the balance of measured tank volumes and cumulative sales. This method requires 15 frequent simultaneous observations of sales and in-tank volumes (i.e. product heights) and temperatures.

The volume of product in a tank is derived by measuring the height of the product and using the geometry of the tank, which is assumed to be known, to 20 compute the corresponding volume. In many instances, tank dimensions vary substantially from assumed design dimensions. Regulatory specifications permit up to 10% variation in length and diameter of cylindrical tanks.

Tank orientation can also cause complications in 25 the calculations. The volume corresponding to a measured height varies substantially when the tank is tilted away from horizontal or rolled away from vertical.

Further, tanks may also fail to conform to a known geometry either through faulty manufacture or 30 installation, or may suffer significant deformation during the course of operations. For example, many fiberglass tanks sag or bend along their length.

In addition, installed tanks are typically inaccessible, and difficult to measure. Thus, it is

- 30 -

necessary to confirm the accuracy of height to volume conversions from generated inventory data and to identify and correct discrepancies where they exist.

The foregoing problems are compounded when two or 5 more tanks are manifolded together. Manifolded tanks are joined together by piping systems and serve common dispensers. Thus, sales quantities from manifolded tanks constitute withdrawals from all tanks in the manifolded system, but not necessarily in equal quantities. Product 10 heights typically vary from tank to tank, but tank geometries, dimensions and orientation may also vary so that a procedure for correcting height to volume conversion errors for a single tank will not apply.

The different factors which influence inventory 15 data manifest themselves in distinct ways which facilitate their identification and correction. These factors are most easily identified by examination of their effects on cumulative departures of actual measured inventory from a theoretical or book value when viewed 20 across a variety of dimensions. In particular, one-time undocumented physical additions or removals of product, e.g. over or under deliveries and pilferage, are evidenced by an addition or subtraction of a constant quantity from the cumulative variance at the time of 25 occurrence and all subsequent observations. Continuous loss of product accumulating over time, e.g. leakage, is evidenced by a loss trend over time. Continuous loss of product varying proportionally with sales value, such a line leak or meter miscalibration, may be determined by 30 identifying a constant negative trend that is cumulative only over periods where delivery lines are pressurized.

A pattern of gains or losses, or both, recurring cyclically as the tank is successively filled and emptied with no long term gain or loss of product, is the pattern 35 associated with height to volume conversion error. The

- 31 -

pattern is cyclical because the error source is identical in each cycle as the tank is filled or emptied. It is distinguishable from the other patterns in that it retraces the same path without the translation which 5 would occur if physical loss or gain of product were taking place.

This problem is most readily diagnosed by analyzing cumulative variance as a function of product height. If the variances are random with no evidence of 10 systematic effects, height to volume conversions may be assumed to be correct. If not, the form of the induced pattern indicates the nature of the conversion error. Thus, an error in tank length induces a linear pattern, an error in tank tilt induces a sinusoidal pattern, and a 15 constant error in tank height measurement induces an arc-like pattern. When other sources of loss or gain are present, the conversion error patterns remain, but are translated in each succeeding filling/emptying cycle to reflect the physical loss of product which has occurred 20 during that cycle. Thus, confusion between conversion errors and other effects can be eliminated.

Sales readings and product height measurements must be made simultaneously. Since the number of 25 observations in any one sales cycle is typically too few to generate a conversion table of sufficient detail to be of practical use, subsequent sales cycles and their corresponding deliveries must be incorporated. If, however, deliveries are unmetered and are used to 30 approximate the volume (as is the standard industry practice), significant inconsistencies are introduced. If an overage or shortage occurs during delivery, then all subsequent sales volumes correspond to tank cross sections which have been shifted upward or downward from 35 their predecessors. Averaging or statistical treatment cannot overcome this deficiency since there is no means

- 32 -

of knowing without metering whether, by how much, and in what direction the data has been shifted.

The procedure of the present invention may include determining if height to volume conversion error is a problem. If the error is a problem, then the system must determine the nature of the problem, e.g. tank dimensions, tank orientation, height measurement or unknown tank geometry, and whether the conversion problem is compounded by other gains and losses. If leakage is suspected, an on-site leak detection investigation is undertaken. In no leakage is indicated, and one or all of tank dimensions, tank orientation and height measurement are problems, new conversion factors are calculated and confirmed using the diagnostic procedures described herein.

If unknown tank geometry or manifolded systems are encountered, the exact current percentage of metered sales actually dispensed from each dispenser is determined by physical measurement. A high order polynomial using a variable of measured product height is used to convert height to volume. The parameters of the polynomial are derived from the differences between measured product height corresponding to the beginning and ending of sales events which do not overlap deliveries.

For a single tank, actual dispensed quantities are regressed using a polynomial based on the differences in measured product height before and after individual sales, subject to the constraint that when the polynomial is evaluated at a height equal to tank diameter, the result is the total tank volume. Observations which include delivery events are discarded.

$$\begin{aligned}
 A_{Sale_i} &= a_1(h_{i-1} - h_i) + a_2(h_{i-1}^2 - h_i^2) + \dots \\
 &\quad + a_n(h_{i-1}^n - h_i^n) \\
 35 \quad Vol &= a_1d + a_2d^2 + \dots + a_nd^n
 \end{aligned}$$

- 33 -

A fifth order polynomial has proven adequate in most cases. Residual analysis may be used to determine adequacy of the polynomial in the presence of severe tank distortions, and higher order polynomials may be introduced as necessary. The number of observations required is determined by estimating a confidence bound around the resulting polynomial with a width adequate for the desired resolution. Thus,

10 $ASale_i$ = Actual dispensed volume in period i .

h_i = Product height upon conclusion of $ASale_i$.

15 h_{i-1} = Product height prior to commencement of $ASale_i$ and after completion of $ASale_{i-1}$.

d = Diameter of tank.

Vol = Total volume of tank.

The converted volume for height h is then given by:

$$Vol(h) = a_1h + a_2h^2 + \dots + a_nh^n$$

20 The omission of a constant term in the regression implies that

$$Vol(h) = 0 \text{ when } h = 0$$

This ensures that the polynomial derived from the height differences is well defined.

25 For manifolded systems, actual sales are regressed simultaneously on individual polynomials based on the various height differences in the several tanks which correspond to a particular sales volume, subject to the constraint that each polynomial evaluated at the 30 corresponding tank diameter yields the total volume of that tank.

$$ASale_i = a_{11}(h_{i-11} - h_{i1}) + a_{21}(h_{i-11}^2 - h_{i1}^2) + \dots + a_{n1}(h_{i-11}^n - h_{i1}^n) + a_{12}(h_{i-12} - h_{i2}) + a_{22}(h_{i-12}^2 - h_{i2}^2)$$

- 34 -

$$\begin{aligned}
 & + \dots + a_{n2}(h_{i-12}^n - h_{i2}^n) + \dots \\
 & + a_{1m}(h_{i-1m} - h_{im}) + a_{2m}(h_{i-1m}^2 - h_{im}^2) \\
 & + \dots + a_{mm}(h_{i-1m}^n - h_{im}^n)
 \end{aligned}$$

where:

5 $ASale_i$ = Actual Sales volume in period i .
 h_{i-1j} = Height of product in tank j after
 completion of $ASale_{i-1}$ and prior to
 commencing $ASale_i$.
 j = 1, 2, . . . m
 10 h_{ij} = Height of product in tank j after
 completion of $ASale_i$.
 m = Number of tanks manifolded.

Volume conversion for the m measured heights, h_1, h_2, \dots
 $\cdot h_m$ in the total system is:

$$15 \quad Vol(h_1, h_2, \dots, h_m) = \sum_{i=1}^m \sum_{j=1}^n a_{ji} h_j^i$$

where:

20 h_i = Height of product measured in the
 i th tank in the manifold.

Delivery inaccuracies have no impact on this
 calculation since all observations made during deliveries
 are discarded. Height changes are related only to the
 corresponding volumes dispensed.

25 Prior determination of actual quantities
 dispensed, as opposed to metered quantities, ensures that
 the only remaining source of error is random measurement
 error. Regression is designed to accommodate random
 error of this kind and to facilitate inferences when
 30 errors are present.

With respect to temperature, the temperature of
 product delivered into a tank system almost invariably
 differs from the temperature of the product already in
 the tank. Its addition has the effect of expanding or

- 35 -

contracting the volume of the combined product. This change in volume can create the appearance of incorrect dimensions of the height to volume conversion, appear as leakage where none exists, or it can mask the existence 5 of actual leakage.

It is therefore preferable, and frequently essential, that all volumes, sales, deliveries and product in storage be converted to a common temperature prior to analysis. Typically 60°F (15°C) is chosen as 10 the standard. The conversion is accomplished as follows:

$$\text{Net Volume} = \text{Gross Volume} (1 - (t-60)\text{CE})$$

where:

t = Measured product temperature in degrees Fahrenheit.

15 CE = Coefficient of expansion.

As above, all calculations are in net gallons of product.

A complication to the calculation may occur if the tank gauges 20, 22, 24 used to measure product volume are designed for static or dormant mode tank testing. Such 20 tank gauges detect leakage when the tank is taken out of service. In this case, product volume changes due to temperature changes during the course of a test must be accounted for.

Further, as shown in Fig. 1, temperature sensors 25 46, 48, 50 are located at different heights in tank 12. If the level of product falls below a given temperature sensor, the corresponding weighted temperature measurement is dropped from the average temperature calculation, and a temperature jump and corresponding 30 volume change may be observed when the net volume is calculated using the new weighted average of temperatures. If uncorrected, such repeated jumps in the data would preclude further analysis of the data for leak detection or the generation of height to volume 35 conversions.

- 36 -

The system of the present invention may be used to overcome these temperature related problems. Using the following definition,

5 $NDB_N =$ The net cumulative variance in the inventory data at observation N.

then,

$$NDB_N = a(1 - (t_0 - 60)CE)$$

$$10 - \sum_{i=1}^N Sa_i(1 - (t_i - 60)CE)$$

$$- V_N(1 - (t_N - 60)CE)$$

where:

a = Gross initial inventory.

15 t_0 = Temperature of initial product volume.

t_i = Temperature of product at observation i.

Sa_i = Gross volume sold in period i.

V_N = Measured gross volume in tank at period N.

CE = Coefficient of expansion.

20 Absent random error or leakage, and assuming no deliveries of product, then

$$NDB_N \approx 0$$

and

- 37 -

$$a(1 - (t_0 - 60)CE)$$

$$- \sum_{i=1}^N Sa_i (1 - (t_i - 60)CE)$$

$$5 \qquad \qquad \approx V_N (1 - (t_N - 60)CE)$$

Therefore, if a temperature jump to temperature t^* occurs at an observation $N + 1$, then

$$\begin{aligned} NDB_{N+1} &= V_N(1 - (t_N - 60)CE) \\ &\quad - Sa_{N+1} (1 - (t^* - 60)CE) \\ 10 &\quad - V_{N+1} (1 - (t^* - 60)CE) \\ &= V_N(1 - (t_N - 60)CE) \\ &\quad - Sa_{N+1} (1 - (t^* - 60)CE) \\ &\quad - (V_N - Sa_{N+1}) (1 - (t^* - 60)CE) \\ &= V_N(t^* - t_N)CE \end{aligned}$$

15 When this final quantity NDB_{N+1} is added to the volume where the transition occurs between temperature sensors, and all subsequent volumes, the effect of the transition is eliminated, and analysis proceeds as it would where individual temperature readings are 20 available.

A large number of variables must be estimated by the software to implement the SIR system of the present invention. For example, as many as forty hoses and independent totalizers per tank system, as well as 25 deliveries numbering four or more per day must be accommodated. Thus, a very large volume of data must be accumulated, encompassing a substantial spread of sales volumes from each totalizer for both the set-up analysis and subsequent routine monitoring. To accommodate this 30 volume of data within current or conceivable future practical computer memory capabilities, the algorithm

- 38 -

implemented by the software utilizes a matrix formulation which invokes the property of a sufficient statistic to reduce the memory requirement.

The calculations used to determine the various 5 error, loss trend and delivery estimates have the form:

$$\begin{aligned} B &= (x^T x)^{-1} x^T y \\ \text{MSE} &= \frac{(y - xB)^T (y - xB)}{m+1} \\ S^2 &= (x^T x)^{-1} \text{MSE} \end{aligned}$$

10 where:

B = Column vector of m parameters to be estimated.
x = Matrix of parameter coefficients.
y = Column vector of independent variables.
15 MSE = Mean squared error.
S² = Variance covariance matrix of parameter estimates.

The values contained in vector y comprise tank 20 gauge readings. The entries in matrix x are measured sales volumes, time, and other constant values. The parameters of vector B which are to be evaluated include the initial volume of the system and subsequent volume changes, including delivery amounts.

For example, if observations are recorded every 25 minute, as many as 1440 rows in the x matrix and the y vector may be recorded. It would clearly be impractical to accumulate and store data in that form over an extended period of time. Instead, data compression techniques are applied so that only a manageable amount 30 of data need be stored.

- .. The algorithm utilizes the property that if an n x m matrix A is partitioned into two submatrices, B and C,

- 39 -

where B is an $i \times m$ matrix and C is a $j \times m$ matrix, such that $i + j = n$, then

$$C^T C = A^T A + B^T B$$

For example,

5

$$\text{if } C = \begin{bmatrix} 1 & 2 \\ 1 & 2 \\ 2 & 1 \\ 1 & 2 \end{bmatrix} \text{ then } A = \begin{bmatrix} 1 & 2 \\ 1 & 2 \end{bmatrix} \text{ and } B = \begin{bmatrix} 2 & 1 \\ 1 & 2 \end{bmatrix}$$

10

$$A^T A = \begin{bmatrix} 1 & 1 \\ 2 & 2 \end{bmatrix} \begin{bmatrix} 1 & 2 \\ 1 & 2 \end{bmatrix} = \begin{bmatrix} 2 & 4 \\ 4 & 8 \end{bmatrix}$$

$$B^T B = \begin{bmatrix} 2 & 1 \\ 1 & 2 \end{bmatrix} \begin{bmatrix} 2 & 1 \\ 1 & 2 \end{bmatrix} = \begin{bmatrix} 5 & 4 \\ 4 & 5 \end{bmatrix}$$

$$\text{Thus, } A^T A + B^T B = \begin{bmatrix} 7 & 8 \\ 8 & 13 \end{bmatrix}$$

15

$$C^T C = \begin{bmatrix} 1 & 1 & 2 & 1 \\ 2 & 2 & 1 & 2 \end{bmatrix} \begin{bmatrix} 1 & 2 \\ 1 & 2 \\ 2 & 1 \\ 1 & 2 \end{bmatrix} = \begin{bmatrix} 7 & 8 \\ 8 & 13 \end{bmatrix}$$

At the conclusion of each 24 hour or other period, 20 only $x^T x$ and $x^T y$ are computed and stored. The matrix x has the form of a square $n \times n$ matrix. Further, the aggregates of observations for different periods are additive, since two square matrices having $n \times n$ dimensions may be added. Thus the total data storage 25 requirement for each period is determined only by the square of the number of parameters of interest.

The system is able to accommodate virtually unlimited numbers of observations by this method of data compression. Without this capability, the system would

- 40 -

not have the storage capacity to accurately and simultaneously estimate the numbers of parameters which are required to perform a statistically significant calculation. This data compression method also allows 5 for processing the data at the facility or for transmitting the data to a host computer for periodic analysis. Figs. 2, 3 and 4 show the Mathcad computer code used to perform the data compression algorithm.

Furthermore, $(x^T x)^{-1} x^T y$ is a complete and 10 sufficient statistic for B. No statistically useful information is lost in the compression. The overall procedure is, therefore, unlimited by memory. The only limitation remaining is the precision available in the computer system used.

15 The software performs SIR analysis, including inventory estimation and leak detection, using the above equation in the following form:

$$\begin{aligned} x &= [1_{\text{range}}, (-1)(T_{\text{range}}), (-1)(S_{\text{range}})^{\text{<meters>}}] \\ y &= (Stk_{\text{range}}) - (CD_{\text{range}}) \end{aligned}$$

20 where:

$$\begin{aligned} \text{range} &= 1 \dots \text{(number of observations)} \\ \text{meters} &= 1 \dots \text{(number of dispensers)} \end{aligned}$$

and

$$\begin{aligned} 1_{\text{range}} &= \text{Column of 1's.} \\ 25 \quad T_{\text{range}} &= \text{Cumulative time in minutes.} \end{aligned}$$

$$(S_{\text{range}})^{\text{<meters>}} = \text{Cumulative sales for an individual dispenser in gallons.}$$

$$30 \quad CD_{\text{range}} = \text{Cumulative deliveries.}$$
$$Stk_{\text{range}} = \text{Tank stick reading in gallons.}$$

To estimate the initial inventory, the matrix x includes a column of unitary values. To estimate loss trends, the matrix x includes a column containing cumulative times of measurement and cumulative sales.

- 41 -

The values of B, MSE and S^2 are then calculated, producing the following result for the vector B:

- 5 B_1 = Estimated initial inventory.
- B_2 = Loss trend.
- $B_{2+meters}$ = Individual meter error.

B is the vector containing the parameter estimates, namely beginning inventory, meter calibrations and loss rate. The loss rate estimate is in the second row (n=2).

- 10 S^2 is the variance covariance matrix of the parameter estimates. Thus, $S_{22} = (S^2)_{22}^{1/2}$ is the standard deviation of the loss rate estimate. Finally, the minimal detectable leak is defined as $t_\alpha S_{22}$, where t_α is the $(1-\alpha)$ percentile of the Student's t distribution.

- 15 The software performs delivery calculations using the equation in the following form:

$$x = [1_{range}, (T_{range})^{(-1)}, (S_{range})^{(-1)}, (D_{range})]$$

$$y = (Stk_{range})$$

20 where:

$range = 1 \dots$ (number of records)

and

- 25 1_{range} = Column of 1's.
- T_{range} = Cumulative time in minutes.
- S_{range} = Cumulative sales in gallons.
- D_{range} = 0 where T_{range} is less than delivery time
 and
 1 where T_{range} is greater than or equal
30 to
 delivery time.

Stk_{range} = Tank stick reading in gallons.

The values of B, MSE and S^2 are then calculated, producing the following result for the vector B:

- 35 B_1 = Estimated initial inventory.
- B_2 = Loss trend.

- 42 -

B_3 = Meter error.

B_4 = Estimated delivery amount.

S^2 is the variance covariance matrix of the estimates. Thus, $S_{44} = (S^2)_{44}^{1/2}$ is the standard deviation of B_4 , the delivery volume estimate. The delivery tolerance is $B_4 t_{\alpha} S_{44}$, where t_{α} is the $(1-\alpha)$ percentile of the Student's t distribution. Delivery tolerances can be reduced to any desired value by increasing the number of observations used in the calculation.

10 The SIR analysis used by the method of the present invention involves computing and comparing cumulative variances. When the initial set-up is complete, computed trend and meter calibrations are used to project forward an expected cumulative variance, that is, the expected 15 value of the difference between gauge readings and computed inventory. Actual cumulative variances are then computed from all subsequent gauge and meter readings and compared to the expected variance.

Figs. 5, 6 and 7 show the routine operation 20 procedure 100 followed by the software to perform this analysis. Data from the set-up of the system and the most recent analysis is entered into the program at step 102. The data entered includes the tank type, tank dimensions, tank tilt, meter calibrations, mean square 25 error and calculated trends. At step 104, three variables established as counters, Counter1, Counter2, and Counter3, are set at zero. The measurement data from the system itself is entered at step 106, namely the 30 readings from the dispenser totalizers, the product height and the product temperature.

The software computes the gross volume of the product, the most recent gross volume and the sales as measured by the individual dispensers at step 108. The software further manipulates the data at step 110 by 35 converting all gross volumes to net volumes, computing

- 43 -

observation to observation variance, and computing cumulative variance. The sign of the cumulative variance is recorded at step 112.

The program proceeds on the basis of the 5 cumulative variance and the value of Counter1 in steps 114, 120, 124, 128, 132, 136 and 140. Depending on the cumulative variance and the value of Counter1, the program analyzes the collected data at step 118 if it is a final observation (step 116), deletes the collected 10 data (steps 122 and 134), performs the analysis for a delivery (step 126) (see below), or reads new data (steps 116, 122, 130, 134, 138 and 142) upon updating the value of Counter1 and other computational variables (i.e. index, sign index and sign). In some cases, collected 15 data is deleted (steps 122 and 134).

Upon computing the rate loss at step 144, the program reads new data at step 146 if the rate loss is not greater than or equal to, e.g., .2 gallon per hour, otherwise it computes the trend of the data at step 148. 20 If at step 150 it is determined that the trend is greater than .2 gallon per hour, a warning is issued at step 156. In either case, the software continues to read and analyze the data at steps 152, 154, 158 and 160 until the last observation.

25 The operation of deleting data 170 is shown in detail in Fig. 8. After performing similar analyses at steps 172, 174, 176, 180 and 184, using the indices and the values of the calculated standard deviations as in the routine operation procedure described above, the 30 values of the counters are updated and new data is read at steps 178, 182, 186 and 188. Data is deleted in accordance with steps 178, 186 and 188.

Finally, Fig. 9 shows the delivery calculation 190 in detail. After determining that the cumulative 35 variance is greater than a predetermined value (three

- 44 -

standard deviations) at step 192, the program determines whether the variance is greater than, e.g., 100 gallons per minute (step 194). If so, the delivery is recorded and the amount of delivered is determined at steps 202 through 220.

If there is a delivery in progress (step 202), data is read until a negative observation to observation variance is observed (step 204). The variance is monitored until the turbulence in the tank subsides (step 10 206). Thirty observations are read (step 208), and all observations from 15 minutes before the delivery until the end of the turbulence observations are deleted (step 210). An indicator variable is introduced with the turbulence observation, from which regression commences 15 (step 212). The confidence bound on the indicator is computed (step 214). If the confidence bound is within a predetermined tolerance, the volume of the delivery is reported within the confidence bounds (step 220); otherwise, additional observations are added, and the 20 confidence bound is recomputed (step 218).

If the variance between data measurements is less than 100 gallons per minute, the software determines whether the gauges are inoperative and reports them as being inoperative (step 198), or proceeds as in the 25 routine operation procedure according to step 200 (in which there is a negative variance) depending on whether the observation exceeds a predetermined value (within one standard deviation) at step 196.

In general, if observed variances are within three 30 standard deviations or other predetermined tolerance of the expected value, the data is stored for future analysis. When cumulative variance exceeds three standard deviations or other predetermined tolerance, different software programs are executed depending on the 35 nature and magnitude of the departure.

- 45 -

If within ten (or other predetermined) successive observations after the initial departure, the cumulative variance returns to within the tolerance range, all data from and including the initial departure and prior to the 5 initial observation are deleted. The time extent and number of observations involved is recorded and stored for, e.g., a daily gauge performance report.

If all ten (or other predetermined) successive observations remain outside the tolerance bound and the 10 cumulative variances are of the same sign, a new trend line is initiated at the point of initial departure. After ten (or other predetermined) additional observations, a third trend line is initiated. If the 15 increment to the overall trend estimated from the most recent observations is not significant, the most recent data is consolidated with the previous data and the process is repeated until such time, if ever, that the current trend increment is significant.

If the departure is positive, the system checks 20 whether the product is being dispensed and whether the gauge height fails to decrease, reflecting removal from tank. If so, the tank gauge is reported to be inoperative.

If the gauge height is increasing, monitoring is 25 continued as above until the most recent trend line returns to its original slope. Minute to minute variances are monitored to detect turbulence until the gauge values again return to within tolerance. All 30 observations which occurred in the fifteen minutes prior to first positive departure until the end of post delivery turbulence are deleted. An indicator variable is introduced at the first observation after post delivery turbulence. The system collects thirty additional observations and performs the regression from

- 46 -

the beginning of the period to determine the volume delivered. The volume delivered is then reported.

If the departure is negative, the system proceeds as with delivery. If successive slope increments fail to 5 show a return to the original slope, indicating continuing loss of product for a predetermined period, typically one hour, and slope exceeds .2 gallon per hour, the system reports a warning that there is a continuous 10 loss of product. If the loss rate is less than .2 gallon per hour but greater than the minimum detectable leak, the system continues to monitor and recalculate the parameters, to be included in a daily operational report. If the incremental trend line shows a return to the 15 original trend, the system proceeds as with delivery, introduces an indicator variable, deletes data as necessary, and performs the regression to determine the volume of product removed. The system reports a one-time removal of product.

Referring to Fig. 10, the invention incorporates a 20 data acquisition and transmission network (DAT Network) 300 to completely automate the process of obtaining, capturing, transferring and processing product inventory data for use in product management, delivery scheduling and environmental compliance practices. DAT network 300 25 includes on-site processors 302, 304 at the facilities 306, 308 where the tanks are located, a customer host processor 310 and a central host processor 312. DAT network 300 links multiple remote facilities 306, 308 to central host processor 312, which performs the SIR 30 analysis. The link may be accomplished indirectly through customer host processor 310, which itself is connected to a plurality of remote facilities 306, 308. Each of these processor elements is composed of 35 independently operating software and hardware systems which form the basis of a wide area network linked by

- 47 -

modems which transmit information electronically via the telephone network 314 using standard dial-up voice grade telephone lines. Examples of DAT networks are the TeleSIRA and ECCOSIRA systems developed by Warren Rogers 5 Associates, Inc., Middletown, Rhode Island.

DAT network 300 provides a uniform method of integrated management for the widest possible variation of underground and above-ground fuel storage, movement and measurement systems. On-site processors 302, 304 are 10 capable of obtaining information from any electronic or mechanical control system, enabling DAT network 300 to accommodate facility configurations that are unique to each facility while presenting the information captured at remote facilities 306, 308 to customer host processor 15 310 or central host processor 312 in a uniform format.

On-line processors 302, 304 obtain and capture product inventory data through the use of proprietary interfaces with external systems in use at remote facility 306, 308, such as tank gauges and sales 20 recording devices. On-line processors 302, 304 transfer captured information daily, weekly or monthly through the public switched telephone network 314 to customer host processor 310 or central host processor 312 for use in inventory management, delivery scheduling and/or 25 environmental compliance. On-site processors 302, 304 may be, e.g., a touch-tone telephones acting as a sending units and Windows-based multi-line, voice prompt/response PC's as the receiving units. On-site processors 302, 304 may be designed to meet the specific needs of facilities 30 306, 308 without requiring remote hardware at the facility in addition to that already present.

In particular, each of on-site processors 302, 304 typically is equipped with an alphanumeric keypad, a character display, a power supply, four programmable 35 serial communication ports, an internal auto-dial/auto-

- 48 -

answer (AD/AA) modem and a local printer port (for connection to a printer). The keypad and display allow for operator configuration and manual entry of sales, delivery and tank level data. Use of an AD/AA 2400 baud 5 modem allows multiple on-site processor 302, 304 to share an existing voice grade telephone line by establishing communication windows to minimize attempted simultaneous use. Each of the programmable serial communication ports is independent, fully programmable and governed by 10 options selected at the facility or off-site through modem access. Finally, on-site processors 302, 304 can prompt the facility operator to enter missing or suspect entries when results are outside the expected range.

The use of customer host processor 310, which is 15 capable of receiving, storing and processing information from multiple on-site processors 302, 304, enables the management of a remote tank population from a single point of contact. A database of information created by customer host processor 310 is the basis for all higher 20 level product management functions performed by DAT network 300. The database is also the basis for the environmental compliance analysis performed by central host processor 312.

The use of central host processor 312, which is 25 capable of receiving, storing and processing the information in the database created by customer host processor 310 for product management enables DAT network 300 to achieve maximum results by utilizing the database for environmental compliance without additional remote 30 facility information or communication. Central host processor 312 is capable of transmitting a resulting database of the environmental analysis back to customer host processor 310 for printing and other customer record-keeping requirements.

- 49 -

The processor elements of DAT network 300 may exhibit other useful operational characteristics. To prevent unauthorized access to DAT network 300, a security access code for dial-up data transfer functions 5 is required. Under secured access, the baud rate, parity, stop bit parameters and communication protocol are determined at any of on-site processors 302, 304, customer host processor 310 or central host processor 312.

10 Another function of DAT network 300 is to monitor tank contents generally. DAT network 300 can be programmed to activate, e.g., an audible and visual alarm if the water level in the tank is too high (e.g., greater than 2 inches), if the product level in the tank is too 15 high (e.g., more than 90% of tank capacity) or too low (e.g., less than 10% of tank capacity, more product must be reordered, less than two days supply), and if a theft occurs (product level changes during quiet periods).

19 The system may be used to obtain valuable 20 information other than inventory regulation and leak detection. For example, the system may incorporate time series analysis routines, including Box Jenkins, moving average and exponential smoothing, to derive estimates of demand for the product which also incorporate temporal 25 and seasonal trends and special events.

The demand analysis may also be combined with additional inputs of holding costs, reorder costs, transportation costs and penalty costs for running out of stock. The system can include optimal inventory 30 algorithms to determine optimal order quantities, reorder points and optimal delivery truck routing. Further, the system may incorporate multiechelon, optimal inventory procedures to accommodate combined wholesale and retail operations, such as with calculus-based optimization and 35 linear, nonlinear and dynamic programming.

- 50 -

Other embodiments are within the scope of the
claims.

- 51 -

What is claimed is:

1. A method of monitoring a fluid storage and dispensing system, said system comprising measurement apparatus for measuring a volume associated with said system, said method comprising:

collecting a plurality of measurement data from said measurement apparatus in a form readable by a computer;

10 storing said plurality of measurement data in a compressed matrix format in a computer memory; and

statistically analyzing said compressed matrix format to determine operational monitoring information.

2. The method of claim 1 wherein said statistically analyzing step includes calculating error 15 data resulting from said measurement apparatus.

3. The method of claim 1 further comprising determining the presence of operational defects in said system.

4. The method of claim 1 further comprising 20 monitoring the accuracy of said measurement apparatus.

5. The method of claim 1 further comprising determining the volume of fluid in said system.

6. The method of claim 1 further comprising 25 determining whether a quantity of fluid removed from said system is caused by a leak in said system.

7. The method of claim 6 further comprising delivering a warning that a leak has been detected in said system.

- 52 -

8. The method of claim 1 wherein said collecting step is performed while said system is operating.

9. The method of claim 8 wherein said collecting step is performed continuously at periodic intervals.

5 10. The method of claim 9 wherein said collecting step is performed automatically under the control of said computer.

11. The method of claim 1 further comprising querying said measurement apparatus under the 10 control of said computer.

12. The method of claim 1 further comprising measuring the temperature of the fluid; and calculating said volume based on the temperature of said volume in said system.

15 13. The method of claim 12 wherein said calculating includes determining a correction value based on a weighted average of the temperature of said volume measured at a plurality of locations within said system.

14. The method of claim 1 wherein said system 20 comprises a plurality of tanks.

15. The method of claim 1 wherein said system comprises an underground storage tank.

16. The method of claim 1 wherein said system comprises an above-ground storage tank.

25 17. The method of claim 1 wherein said system comprises a partially above-ground storage tank.

- 53 -

18. The method of claim 1 wherein said storing step comprises generating said compressed matrix format as a product of a data matrix and the transpose of said data matrix.

5 19. The method of claim 18 wherein said product is formed by addition of partial products of each of a plurality of partitions of said data matrix with the transpose of each said partition.

20. The method of claim 1 wherein said measurement apparatus includes a volumetric gauge, a dispensing apparatus and a sales recording device.

21. The method of claim 1 further comprising transmitting said measurement data to a host processor to perform said statistically analyzing step.

15 22. The method of claim 1 further comprising transmitting said compressed matrix format to a host computer to perform said statistically analyzing step.

23. The method of claim 1 wherein said collecting 20 step comprises estimating an initial volume of fluid in said system.

- 54 -

24. A method of monitoring a fluid storage and dispensing system, said system comprising measurement apparatus for measuring a volume associated with said system, said method comprising:

5 collecting a plurality of measurement data from said measurement apparatus in a form readable by a computer;

 storing said plurality of measurement data in a compressed matrix format in a computer memory;

10 statistically analyzing said compressed matrix format;

 determining whether a quantity of fluid removed from said system is caused by a leak in said system; and

15 delivering a warning that a leak has been detected in said system.

25. An apparatus for monitoring a fluid storage and dispensing system, said apparatus comprising:

 measurement apparatus for measuring a volume associated with said system; and

20 a computer comprising a processing means for collecting a plurality of measurement data from said measurement apparatus and a memory for storing said plurality of measurement data in a compressed matrix format;

25 wherein said processing means performs statistical analysis of said compressed matrix format to determine operational monitoring information.

26. The apparatus of claim 25 wherein said system comprises a plurality of tanks.

30 27. The apparatus of claim 25 wherein said system comprises an underground storage tank.

- 55 -

28. The apparatus of claim 25 wherein said system comprises an above-ground storage tank.

29. The apparatus of claim 25 wherein said system comprises a partially above-ground storage tank.

5 30. The apparatus of claim 25 wherein said measurement apparatus includes a volumetric gauge, a dispensing apparatus and a sales recording device.

31. The apparatus of claim 30 wherein said volumetric gauge comprises a probe disposed in said 10 system.

32. The apparatus of claim 31 wherein said probe is a magnetostrictive tank probe.

33. The apparatus of claim 30 wherein said dispensing apparatus comprises a totalizer.

15 34. The apparatus of claim 30 wherein said sales recording device simulates operation of a point of sale terminal.

35. The apparatus of claim 25 further comprising a temperature sensor disposed within said system 20 in contact with said volume for obtaining a temperature measurement of said volume.

36. The apparatus of claim 35 wherein said temperature measurement is used to calculate said volume.

- 56 -

37. The apparatus of claim 25 further comprising a plurality of temperature sensors disposed at different locations within said system, each of said sensors being in contact with said volume for obtaining a 5 plurality of temperature measurements of said volume.

38. The apparatus of claim 37 wherein said temperature measurements are used to calculate said volume.

39. The apparatus of claim 25 wherein said 10 measurement data is collected simultaneously from said various measurement apparatus.

40. The apparatus of claim 25 wherein said measurement data obtained from said measurement apparatus are transmitted to said computer.

15 41. The apparatus of claim 25 further comprising a host processor remote from said computer to perform said statistical analysis.

42. The apparatus of claim 25 wherein said compressed matrix format is generated as a product of a 20 data matrix and the transpose of said data matrix.

43. The apparatus of claim 42 wherein said product is formed by addition of partial products of each of a plurality of partitions of said data matrix with the transpose of each said partition.

- 57 -

44. A method of monitoring a fluid storage and dispensing system, said system comprising a plurality of measurement apparatus for measuring a volume associated with said system, said method comprising:

- 5 simultaneously collecting measurement data from said plurality of measurement apparatus in a form readable by a computer to determine a change in said volume;
- 10 repeating said collecting step to obtain a plurality of said measurement data from said plurality of measurement apparatus;
- 15 storing said plurality of measurement data in a compressed matrix format in a computer memory; and
- 20 statistically analyzing said compressed matrix format to determine operational monitoring information.

45. The method of claim 44 further comprising estimating an initial value of said volume during said analyzing step.

- 58 -

46. A method of monitoring a fluid storage and dispensing system, said system comprising measurement apparatus for measuring a volume associated with said system and a plurality of temperature sensing devices 5 located at different heights in said system, said volume having a height in said system, said method comprising:

collecting a plurality of volume measurement data from said measurement apparatus in a form readable by a computer;

10 adjusting said volume measurement data based on temperature measurements taken from those of said plurality of temperature sensing devices at a height below the height of the volume in said system;

15 storing said plurality of volume measurement data in a compressed matrix format in a computer memory; and statistically analyzing said compressed matrix format to determine operational monitoring information.

47. A method of determining a volume associated with a fluid storage and dispensing system, said volume 20 having a height in said system, said system comprising measurement apparatus for measuring said height, said method comprising:

collecting a plurality of height measurement data from said measurement apparatus in a form readable by a 25 computer;

storing said plurality of height measurement data in a compressed matrix format in a computer memory; and performing regression analysis using said compressed matrix format to calculate said volume 30 associated with said system.

48. The method of claim 47 wherein said collecting step is performed each time a portion of said volume is dispensed from said system.

- 59 -

49. The method of claim 48 wherein said collecting step is not performed when said fluid is being added to said system.

50. An apparatus for determining a volume associated with a fluid storage and dispensing system, said volume having a height in said system, said apparatus comprising:

measurement apparatus for measuring said height of said volume; and

10 a computer comprising a processing means for collecting a plurality of height measurement data from said measurement apparatus and a memory for storing said plurality of height measurement data in a compressed matrix format;

15 wherein said processing means performs regression analysis of said compressed matrix format to determine said volume associated with said system.

51. A method of determining a plurality of volumes, each of said volumes associated with one of a plurality of fluid storage and dispensing systems, each of said volumes having a height in its associated system, each of said systems comprising measurement apparatus for measuring said height for each of said volumes, said method comprising:

25 collecting a plurality of height measurement data from said measurement apparatus of each of said plurality of systems in a form readable by a computer;

storing said plurality of height measurement data in a compressed matrix format in a computer memory; and

30 performing regression analysis using said compressed matrix format to calculate said volumes associated with said systems.
